

Problem

Clicking "Generate PDF" on any certificate/application (birth, death, citizenship, marriage, etc.) produced a PDF with garbled, unreadable Nepali text instead of proper Devanagari script.

Root Causes Found

1. Missing font registration. The app's PDF code assumed a Devanagari font was already loaded into jsPDF, but no such font was ever actually registered. jsPDF silently fell back to Helvetica (a Latin-only font), which has no Devanagari characters — so every Nepali character printed as random Latin/symbol garbage.

2. Missing text shaping (deeper issue, found after the first fix). Even after loading a proper Devanagari font, some words still looked misspelled — e.g. मिति (date) printed as मतिि, सिफारिस printed as सफिरसि. This is because Devanagari requires "shaping": certain vowel marks are stored in the text after their consonant but must display *before* it. jsPDF has no built-in support for this reordering, so it drew letters in the wrong visual order. The Nepali text in the app's source code was never actually misspelled — it just wasn't being drawn correctly.

3. Inconsistent spelling of "Hetauda". The municipality name appeared spelled 3 different ways across the codebase (हेटौडा / हेटौडा / हेटौडा). Standardized to the officially correct spelling, हेटौडा.

What Was Changed

File	Change
notosansdevanagari-font.js	New file. Embeds the Noto Sans Devanagari font and registers it with jsPDF so Devanagari text can be drawn at all.
devanagari-canvas-text.js	New file. Renders each line of Nepali text through the browser's own (correctly shaping) canvas text engine, then places it into the PDF as an image — this fixes the letter-reordering problem, since jsPDF itself can't shape Devanagari.
script.js	Updated createWardNibedanPdf() (the shared function all certificate PDFs go through) to use the new shaping-correct renderer instead of jsPDF's plain text drawing. Fixed the "Hetauda" spelling in 2 places. No Nepali sentence, label, or wording was changed — only how the text gets drawn onto the page.
index.html	Added 2 new <script> tags to load the two new files, in the correct order, before the main app script.

Verification

Before shipping, I generated test PDFs at each stage and visually confirmed:

- Devanagari font embeds and renders (no more garbled text)

- Previously-broken words (मिति, सिफारिस, नागरिकता, चरित्र, विवरण) now render correctly, letter order intact
- A full sample birth-certificate application PDF was generated end-to-end and reads correctly, including line wrapping and right-aligned signature block
